

Learnability at the RKHS boundary

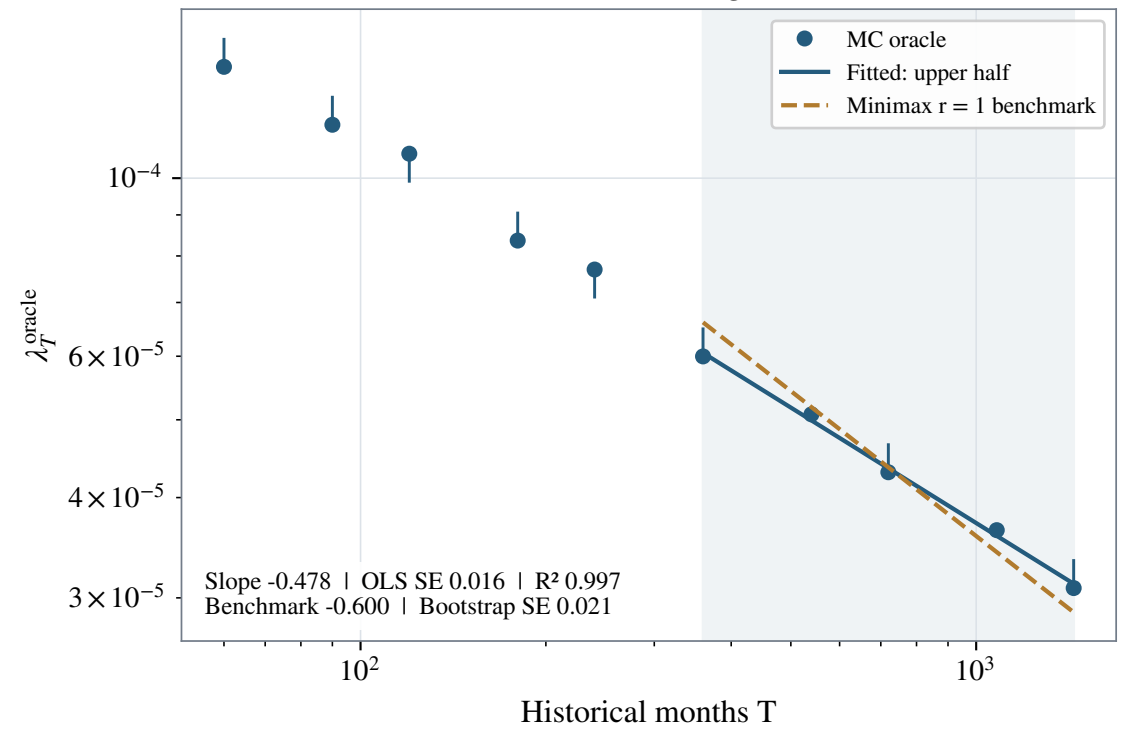

$b = 1.5$ | 5,000 stocks | 2,000 directions | 500 independent paths

Target: $1/[\sqrt{j} \log(j+1)]$. Infinite-sequence $r = 1$ only; logarithmic corrections and finite J affect observed slopes.

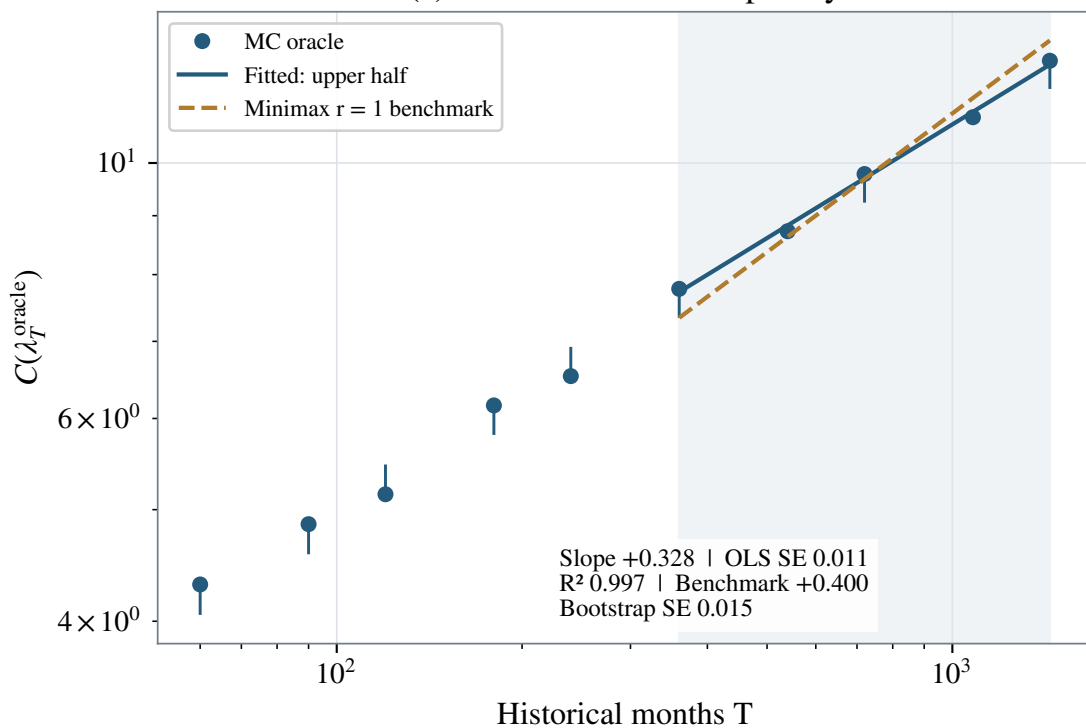

(a) Finite-sample learnability map

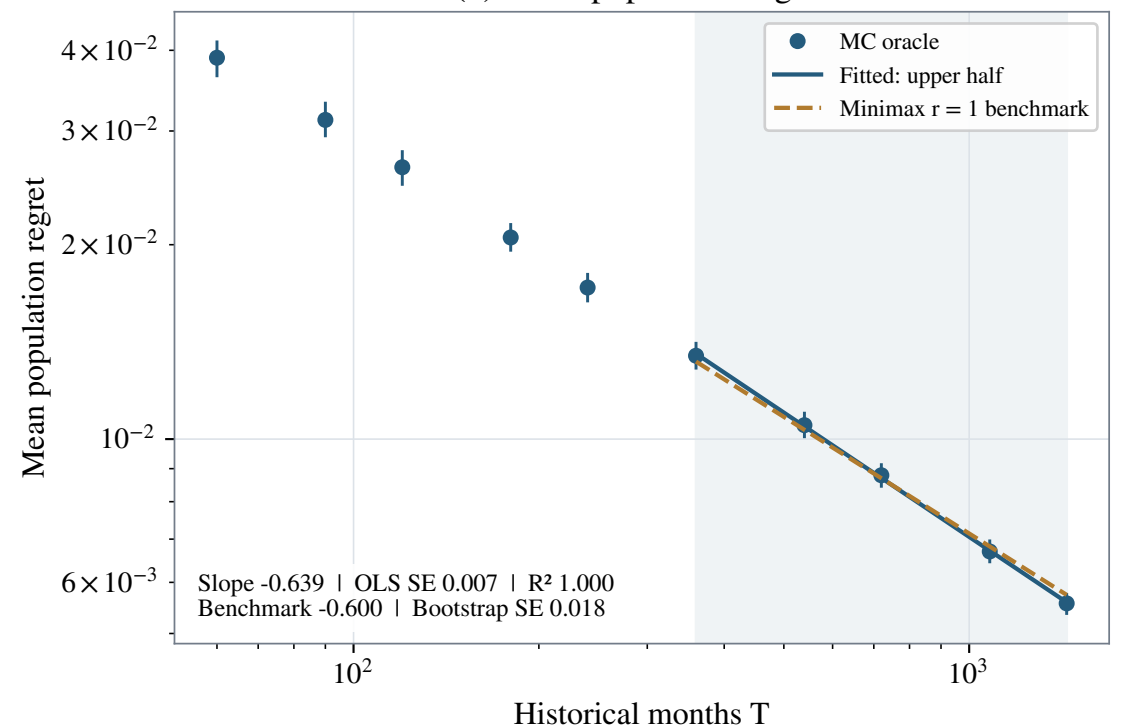

(b) Oracle ridge

(c) Oracle effective complexity

(d) Exact population regret

Risk is evaluated analytically, not on a simulated test set. Bars: 95% bootstrap intervals across independent paths.

Slope fits use the predeclared upper half, $T = 360-1,440$ (shaded); all sample sizes remain visible.

Dashed slopes are minimax $r = 1$ benchmarks, not predicted DGP-specific oracle rates.

The full C/T range is shown on a log axis and can exceed one. Median validation markers do not describe mean validation risk.
